

# The Development of Large-Area Psec TOF Systems

Henry J. Frisch  
Enrico Fermi Institute and Physics Dept  
University of Chicago

# Introduction

- Resolution on time measurements translates into resolution in space, which in turn impact momentum and energy measurements.
- Silicon Strip Detectors and Pixels have reduced position resolutions to  $\sim 5\text{-}10$  microns or better.
- Time resolution hasn't kept pace- not much changed since the 60's in large-scale TOF system resolutions and technologies (thick scint. or crystals, PM's, NIM/Camac/VME TDC's)
- Improving time measurements is fundamental, and can affect many fields: particle physics, medical imaging, accelerators, astro and nuclear physics, laser ranging, ....
- Need to understand what are the limiting underlying physical processes- e.g. source line widths, photon statistics,  $e/\text{photon}$  path length variations.
- **What is the ultimate limit for different applications?**

# OUTLINE

1. Introduction: why picosec, and why 'large-area'?
2. HEP needs: particles and quark flow, heavy particles, displaced vertices, photon origin
3. Three key developments since the 60's: MicroChannel Plates (MCPs), 200 GHz electronics, and 'end-to-end' simulation
4. The need for 'end-to-end' simulation
5. Positron-Emission Tomography (PET): looks like HEP: data rate, # of channels, S/N, data-acquisition, real-time imaging (not my area..)
6. What determines the ultimate limits?  
Applications?

Timothy Credo IMSA senior (Harvard next year)  
Robert Schroll Theory grad student (Physics335)  
Shreyas Baht UC undergrad- just joined  
Fukun Tang EFI Electronics Engineer  
Harold Sanders Head, EFI Elec. Devel. Gp.  
HJF

Many thanks to Katsushi Arisaka (UCLA), Alan Bross (FNAL), Paul Hink (Burle), Mario Kasahara (Hamamatsu), Bruce Laprade (Burle), John Martin (Burle), and Wilma Raso (Burle), and to Joe Lykken and Maria Spiropulu for causing this.

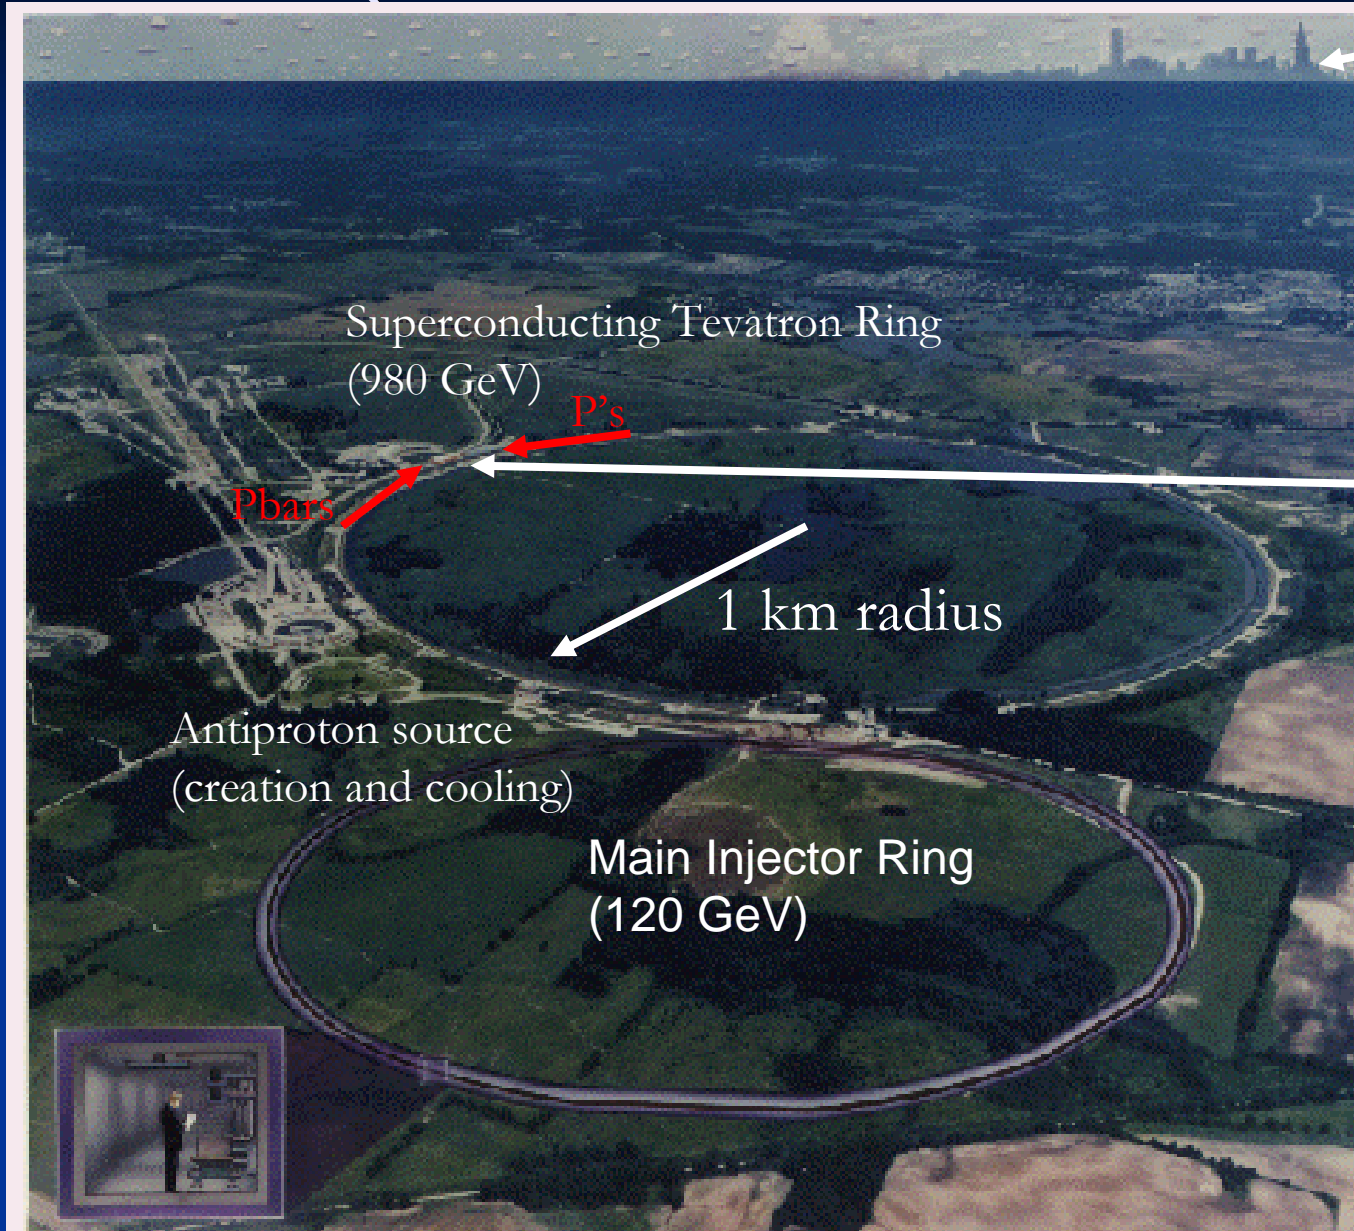

**Now with David Yu , Jakob Van Santen (students), Karen Byrum (physicist) and Gary Drake (Elec. Engineer) of Argonne National Lab, and Prof.'s Chin-Tu Chen and Chien-Minh Kao of the Dept of Radiology, Univ. of Chicago. Also have a MOU in progress with Saclay in France, and a close working relationship to Jerry Va'vra at SLAC. Have developed a community (e.g. Saclay workshop)**

My motivation- High Energy Collisions- understanding the basic forces and particles of nature- hopefully reflecting underlying symmetries

The CDF detector at Fermilab- 5000 tons... more than a million channels

# Fermilab (40 miles west of Chicago)

Superconducting Tevatron Ring  
(980 GeV)

Pbars

P's

1 km radius

Antiproton source  
(creation and cooling)

Main Injector Ring  
(120 GeV)

CDF is here

We give tours-  
come visit!

# The unexplained structure of basic building blocks-e.g. quarks

The up and down quarks are light (few MeV), but one can trace the others by measuring the mass of the particles containing them. Different models of the forces and symmetries predict different processes that are distinguishable by identifying the quarks. Hence my own interest.

$Q=2/3$

$M \sim 2 \text{ MeV}$

Up

$M = 1750 \text{ MeV}$

Charm

$M = 175,000 \text{ MeV}$

Top

$Q=-1/3$

$M \sim 2 \text{ MeV}$

Down

$M = 300 \text{ MeV}$

Strange

$M = 4,500 \text{ MeV}$

Bottom

# 2 TeV ( $> 3$ ergs) pbar-p collisions

(apologies for blurriness-ps to pdf to ppt...)

The Basics- Page 1

Figure 2:

For each track,  $\beta = L/\Delta t$ , where  $L \equiv$  track length (helix) from vertex to outer radius, and:

$\Delta t =$  (time at outer radius  $- t_0$ ), where  $t_0$  is the time of interaction.

## Beam's Eye View

The Basics- Page 2

Figure 3:

R-Z (side) view of the same event. Note the mis-reconstructed tracks in this view (no slouch detector-96 layers of COT, 7 or 8 silicon).

## Side View

$\sim 10$  million collisions/sec; 1 million electronics channels

IBM Psec Timing

# The basics of particle ID by TOF

## What sets the 1 psec goal for HEP?

The Basics- Identifying particles by measuring velocity and momentum.

Identifying particles by measuring velocity and momentum.

Particle masses:  $e$  : 0.00051 MeV;  $\mu^-$ :105.7 MeV; $\pi^+$ : 139.6 MeV;  $K^+$ : 493.7 MeV;  $p$ : 938.3 MeV;

Basic Special Relativity in HEP units (electrical engineers in the audience)

Work in nsec and feet  $\implies c=1$ :

$$\beta \equiv v/c; \gamma \equiv \frac{1}{\sqrt{1-\beta^2}}; E^2 = p^2 + m^2; \quad (1)$$

What we need is  $p = \beta\gamma m$ . Solve for m given p and  $\beta$ .

Measure p from the curvature in the field, and  $\beta$  (and hence  $\gamma$ ) from the time-of-transit and length of the trajectory.

Separation with a 1.5-m Radius Solenoid (CDF)

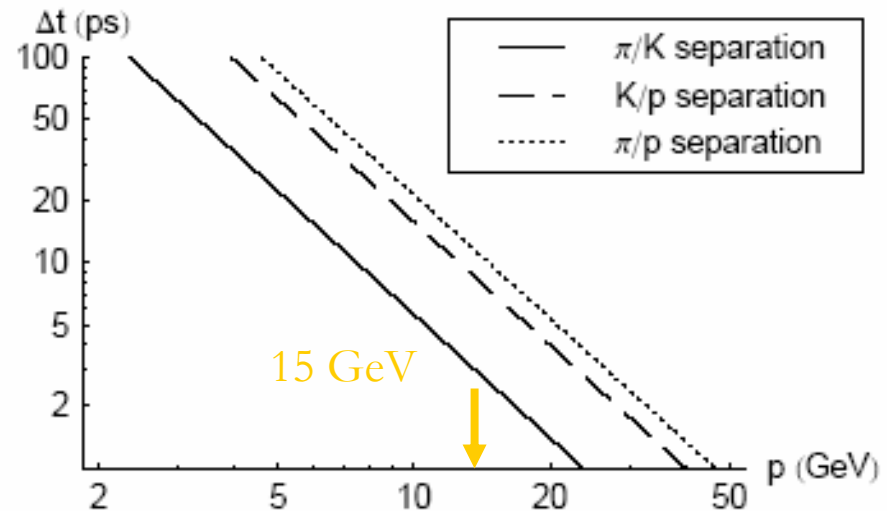

Figure 4: Contours of 1-sigma separation for pions, kaons, and protons versus the time resolution of the particle flight time over a 1.5-meter path for a detector with 1psec resolution.

# A real CDF Top Quark Event

$T\text{-}\bar{T} \rightarrow W^+bW^-b\bar{b}$

Can we follow the color flow through kaons, cham, bottom? TOF!

# Why has 100 psec been the # for 60 yrs?

Typical path lengths for light and electrons are set by physical dimensions of the light collection and amplifying device.

These are now on the order of an inch. One inch is 100 psec  
That's what we measure- no surprise! (pictures from T. Credo)

Typical Light Source (With Bounces)

Typical Detection Device (With Long Path Lengths)

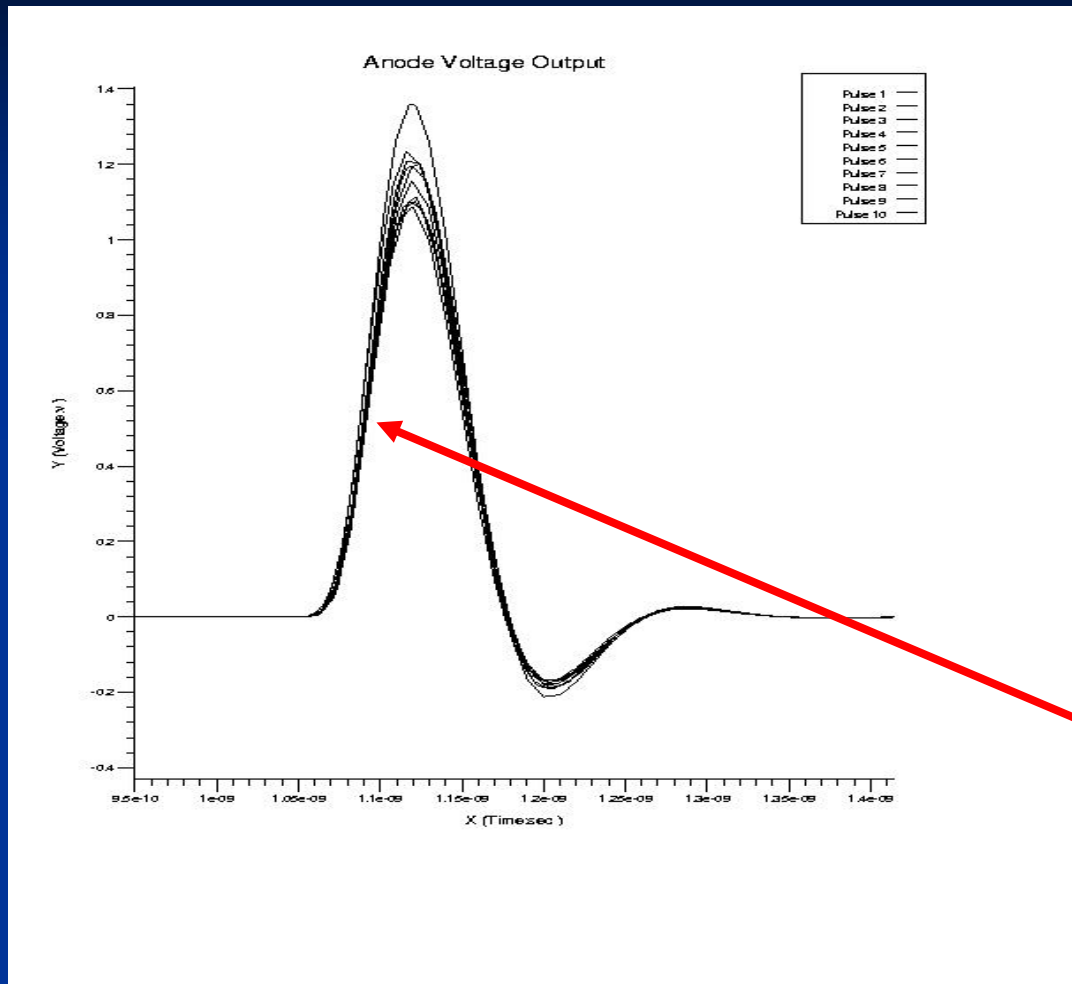

# Major advances for TOF measurements:

Micro-  
photograph of  
Burle 25 micron  
tube- Greg  
Sellberg  
(Fermilab)

**1. Development of MCP's with 6-10 micron pore diameters (300 micron = 1 psec)**

# Major advances for TOF measurements:

Output at anode  
from simulation of  
10 particles going  
through fused  
quartz window- T.  
Credo, R. Schroll

Jitter on  
leading  
edge 0.86  
psec

2. Ability to simulate electronics and systems  
to predict design performance

# Major advances for TOF measurements:

## SIM-IV: TAC Outputs vs. Tw Inputs

Sweep Tw from 1ns to 1.01ns with 1ps

Increment

Simulation  
with IHP  
Gen3 SiGe  
process-  
Fukun Tang  
(EFI-EDG)

3. Electronics with typical gate jitters  $\ll 1$  psec

# Major advances for TOF measurements:

Most Recent work-

IBM 8HP  
SiGe process  
See talk by  
Fukun Tang  
(EFI-EDG) at  
Saclay wkshp

<http://hep.uchicago.edu/psec/conf.html>

3a. Oscillator with predicted jitter  $\sim 5$  femtosec (!)  
(basis for PLL for our 1-psec TDC) .

# Solutions: Generating the signal

**Use Cherenkov light - fast**

Custom Anode with  
Equal-Time Transmission  
Lines + Capacitive. Return

A 2" x 2" MCP-  
actual thickness  
~3/4"

e.g. Burle  
(Photonis) 85022-  
with mods per  
our work

# Geometry for a Collider Detector

2" by 2"  
MCP's

Typical Area:  
28 sq m (CDF)  
25 sq m (LHC)  
=>10K MCP's

Space in the radial direction is expensive- need a thin segmented detector

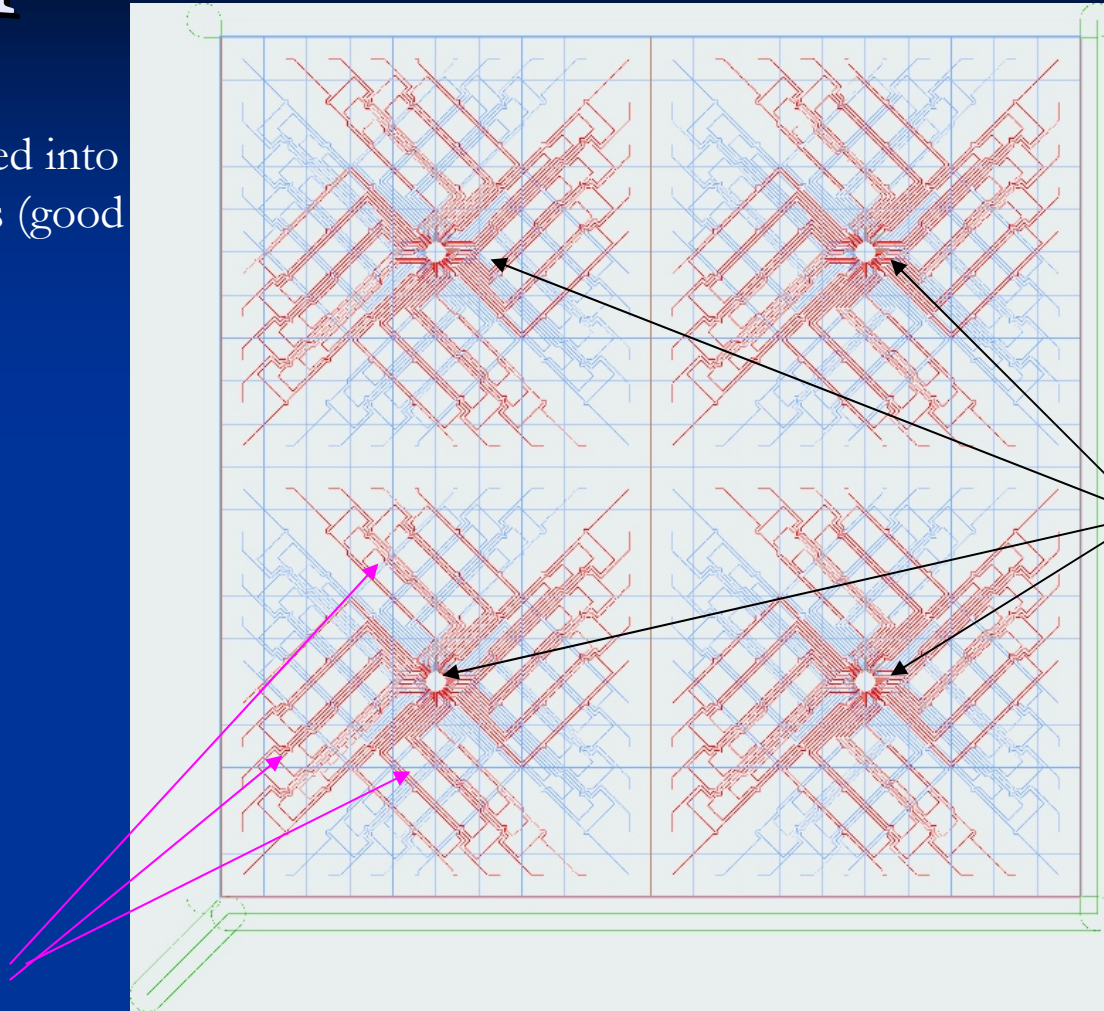

# Small dim. Anode Structure?

1. RF Transmission Lines
2. Summing smaller anode pads into 1" by 1" readout pixels
3. An equal time sum-make transmission lines equal propagation times
4. Work on leading edge- ringing not a problem for this fine segmentation

# Equal-Time Collector Anode

Module divided into  
4 1"x1" pixels (good  
for CDF,e.g)

**4 differential  
outputs-  
each to a  
200:1 `time  
stretcher'  
chip (ASIC)  
directly on  
back of  
module**

**Equal-time transmission-line traces to  
differential output pins (S and R)**

# Anode Return Path Problem

Current out of MCP is inherently fast- but return path depends on where in the tube the signal is, and can be long and so rise-time is variable

Would like to have return path be short, and located right next to signal current crossing MCP-OUT to Anode Gap

↓ ↑  
S R

# Capacitive Return Path Proposal

Return Current from anode

Current from MCP-OUT

**Proposal: Decrease MCP-OUT to Anode gap and capacitively couple the return (?)**

# Solving the return-path problem (?)- Add a grid to the anode layout

# Mounting electronics on back of MCP- matching

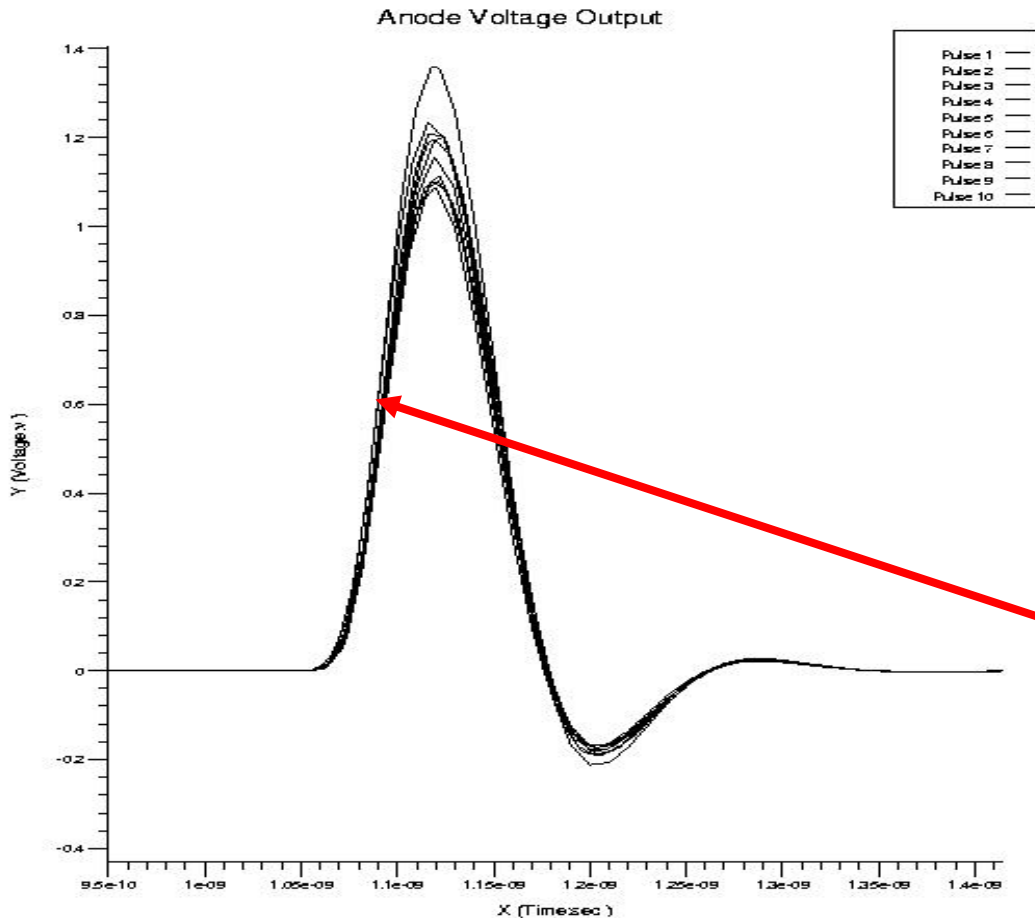

Conducting Epoxy-  
machine deposited  
by Greg Sellberg  
(Fermilab)

Temporary Solution  
for prototyping- can  
have custom anodes  
built and installed in  
MCP

(\$, but more so  
time...)

# End-to-End Simulation Result

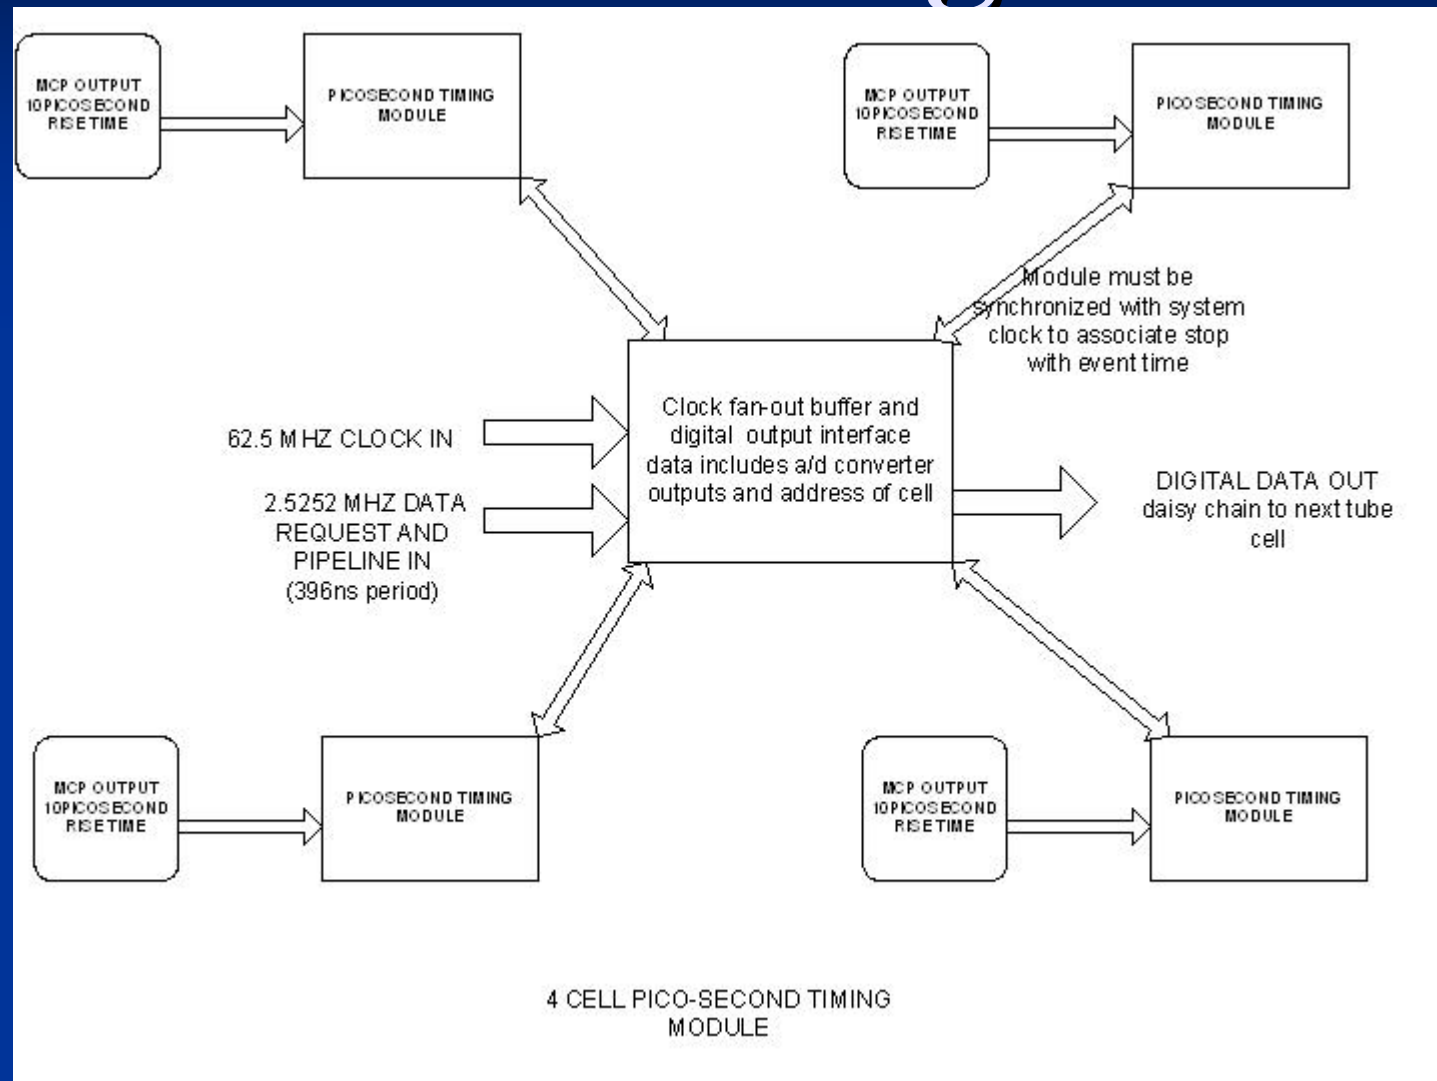

Output at anode  
from simulation of  
10 particles going  
through fused  
quartz window- T.  
Credo, R. Schroll

Jitter on  
leading  
edge 0.86  
psec

# EDG's Unique Capabilities - Harold's Design for Readout

Each module has 5 chips- 4 TDC chips (one per quadrant) and a DAQ 'mother' chip.

Problems are stability, calibration, rel. phase, noise.

Both chips are underway

# Placement of chips on module

Module divided into  
4 1"x1" pixels (good  
for CDF, e.g)

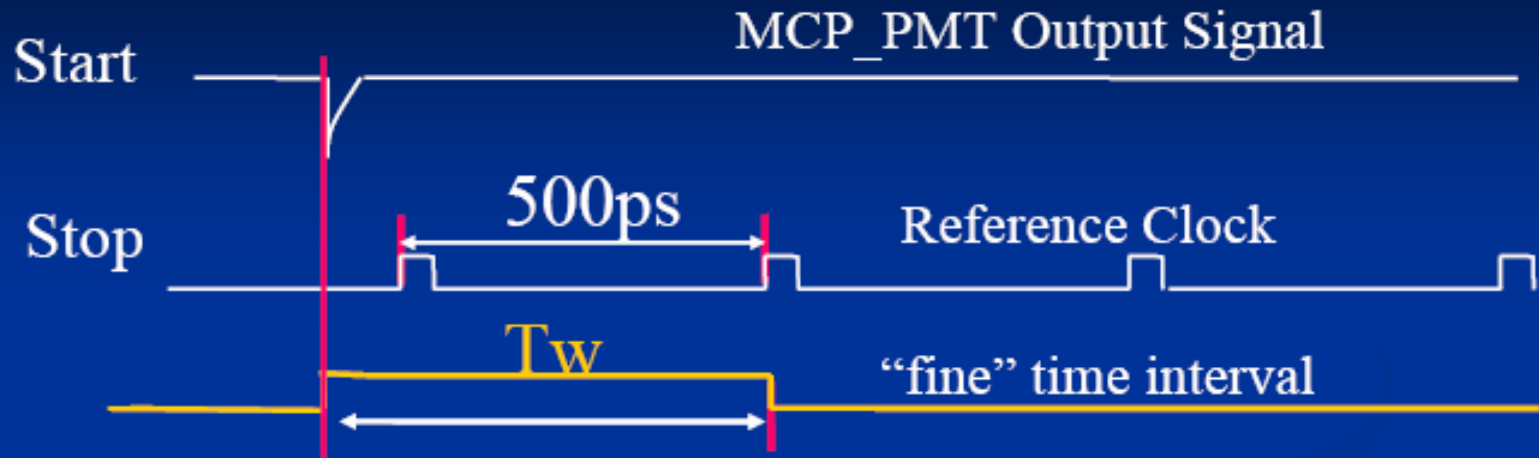

'DAQ' Chip  
TDC, digital  
readout, clock  
distribution,  
calibration,  
housekeeping

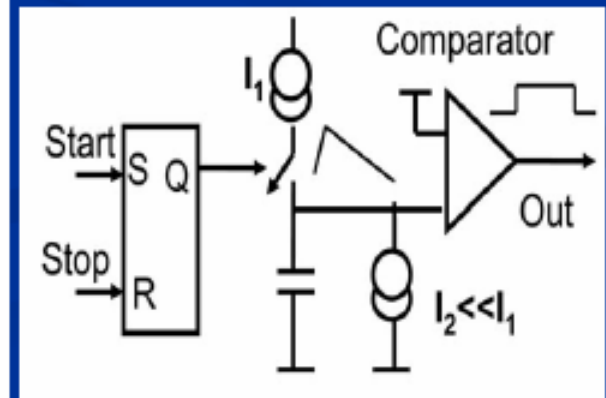

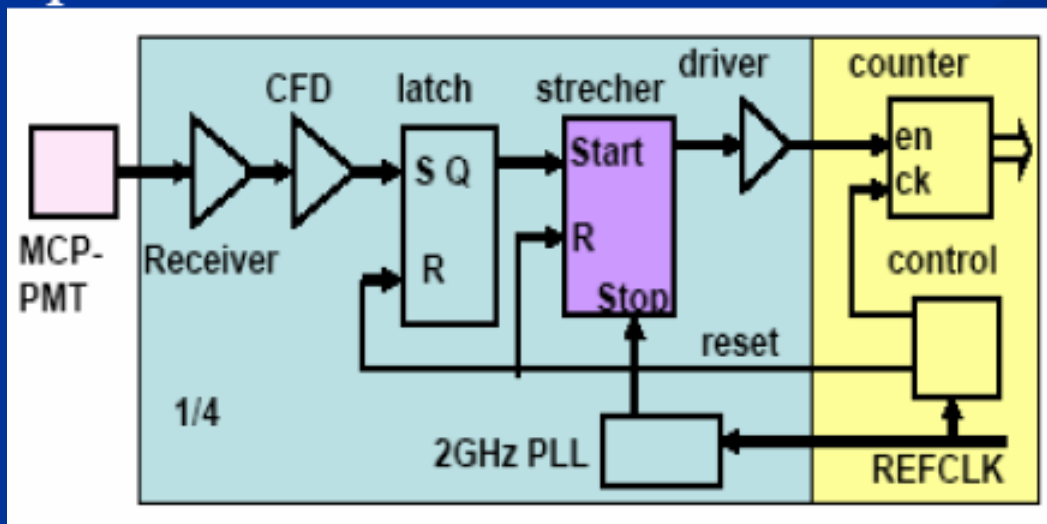

200:1 'time  
stretcher'  
chips

Equal-time transmission-line traces to  
differential output pins (S and R)

# Proposed Time Stretcher TDC with 1ps Resolution

## psFront-end

## Electronics Requirements & Process Evaluations

<i>Input signal bandwidth:</i>	<i>~23.3GHz</i>
<i>Input signal width (FWHM):</i>	<i>~40ps</i>
<i>TDC resolution:</i>	<i>~1ps</i>

### Minimum Requirements:

- **ultra low noise, ultra high  $f_T$  transistors**  
     > 5-10x of the input signal bandwidth *~(110-220GHz)*
- **stable passive components**  
     Inductors, MIM Capacitors, Resistors, Varactors ...

### Available Processes:

- **IHP SiGe BiCMOS 0.25 $\mu$ m technology:**  
     (SG25H1, SG25H2) --- *Europpractice*
- **IBM SiGe BiCMOS 0.13 $\mu$ m Technology:**  
     (8HP) --- *MOSIS*

Saclay, France March 8-9 2007

# Microphotograph of IHP VCO Chip (submitted through Europractice)

Taken at Fermilab by  
Hogan –

Design by Fukun Tang

Affordable: <10K/shot

Training Classes (Europe)

But- meager technical  
support, libraries, ... (nice  
folks tho- structural)

# So, switched to IBM 8HP- same 2-GHz VCO in 8HP

Fukun Tang, UC

UC Designed 2GHz VCO Chip with 5 fsec Cycle-to-Cycle Time Jitter  
Using IBM 0.13 $\mu$ m SiGe BiCMOS8HP Process (Feb. 2007)

# 2GHz VCO Design using IBM SiGe BiCMOS8HP Process

EDA Tools:

Cadence Virtuoso  
Analog Environment

Verification Tools:

Diva/Assura

## Simplified VCO Schematic

- Purely hetero-junction transistors
- Negative resistance
- On-chip high-Q LC tank
- High Frequency PN diode Varactors
- Capacitor voltage dividers
- 130Mhz tuning range
- Full differential 50-ohm line drivers

Core

## Output Phase Noise Spectra Plot

Phase Noise; dBc/Hz, Relative Harmonic = 1

## Periodic Noise Response

# DAQ Chip- 1/module

Figure 11: Altera development board with USB JTAG interface.

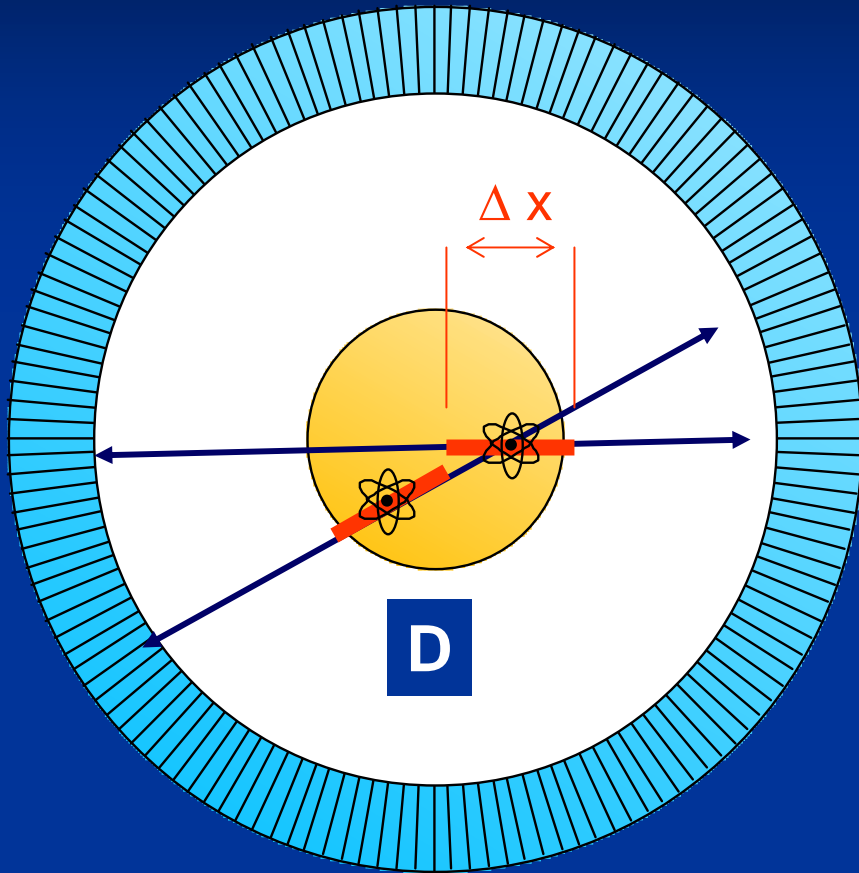

- Jakob Van Santen (4<sup>th</sup> yr undergrad) implemented the DAQ chip functionality in an Altera FPGA- tool-rich environment allowed simulation of the functionality and VHDL output
- ASIC will be designed at Argonne by John Anderson and Gary Drake.
- Again, simulation means one doesn't have to do trial-and-error.

# Why is simulation essential?

- Want optimized MCP/Photodetector design-complex problem in electrostatics, fast circuits, surface physics, ....
- Want maximum performance without trial-and-error optimization (time, cost, performance)
- At these speeds ( $\sim 1$  psec) cannot probe electronics
- Debugging is impossible any other way.

# Time-of-Flight Tomograph

Slide from Chin-Tu Chen (UC) talk at Saclay Workshop

- *depends on timing resolution of detectors*

- *weighted back-projection along line-of-response (LOR)*

$$\begin{aligned}\Delta x &= \text{uncertainty in position along LOR} \\ &= c \cdot \Delta t / 2\end{aligned}$$

no TOF

300 ps TOF

Our goal is 30 psec TOF+reconstruction

## Benefit of TOF

*Better image quality*

*Faster scan time*

- 5Mcts TOF    ○ 5Mcts
- 1Mcts TOF    ● 1Mcts

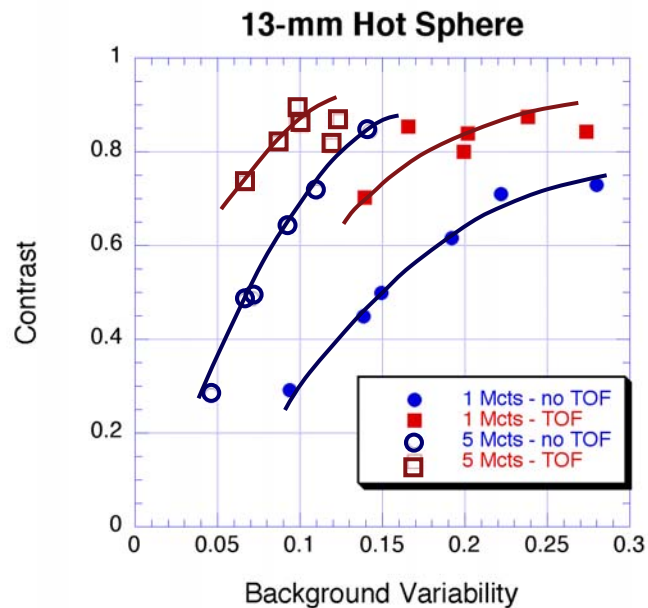

1 Mcts

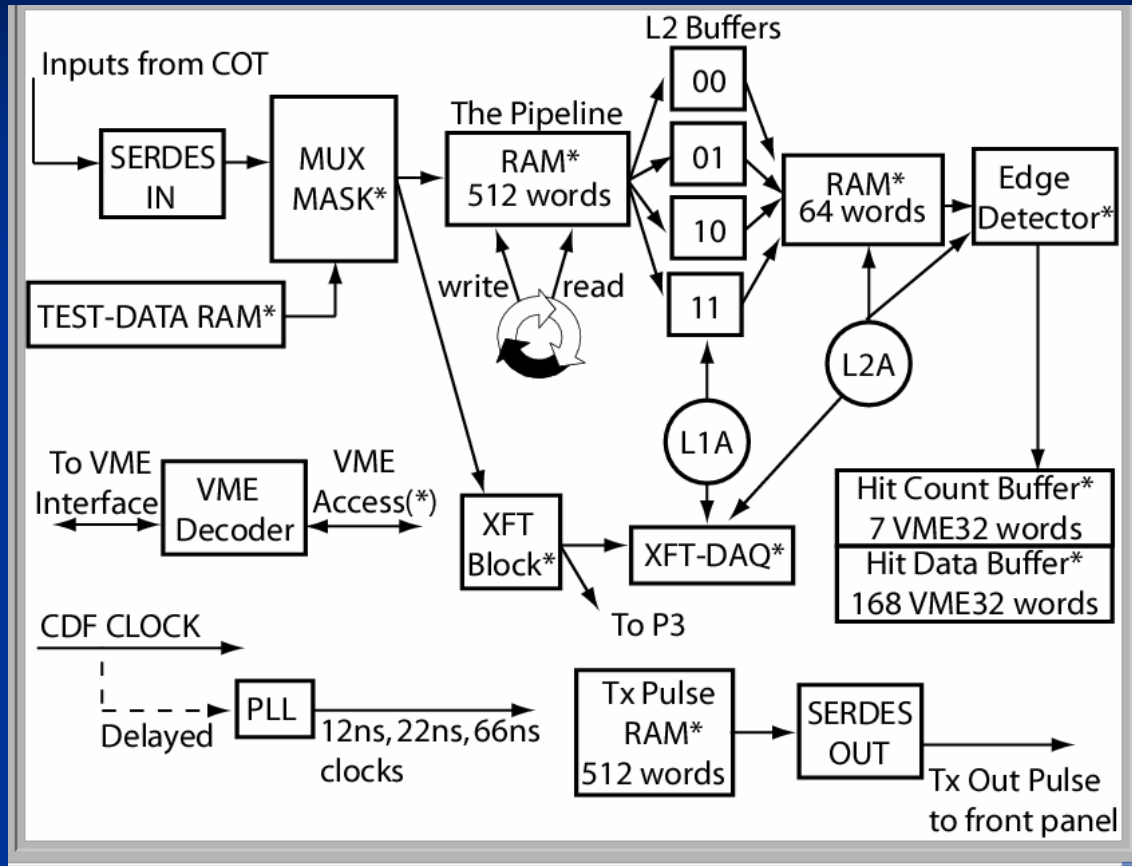

5 Mcts

10 Mcts

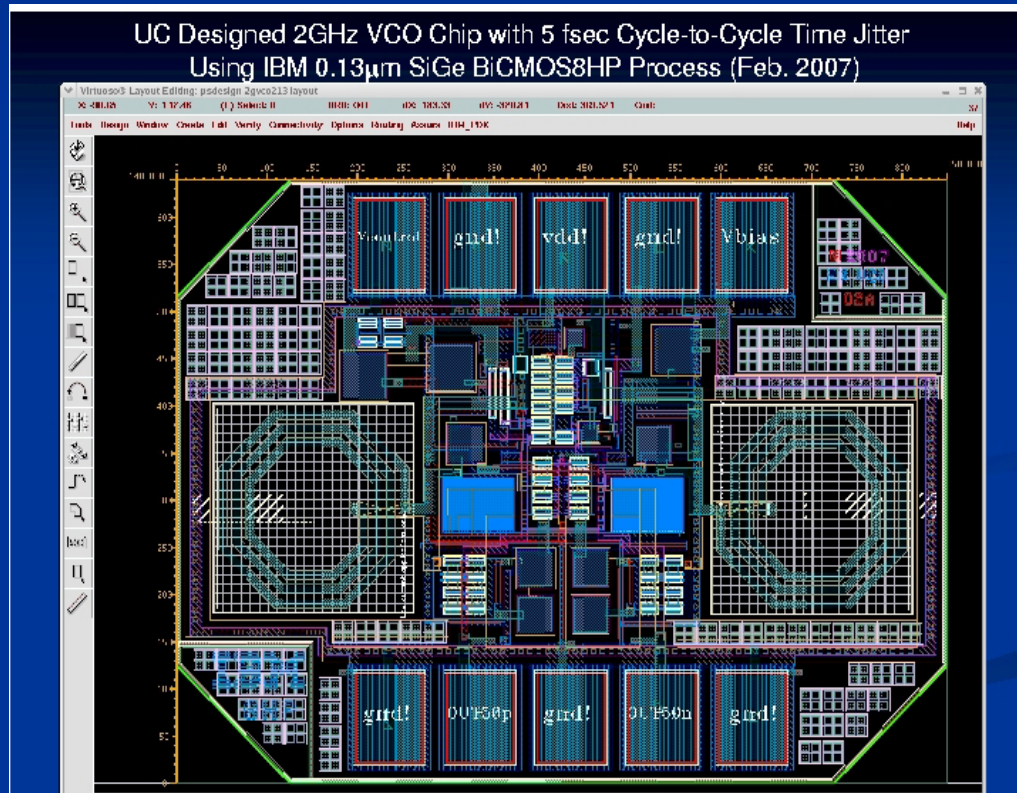

# Back-end Processing for PET

Example of a TDC for CDF we designed in Altera- has trigger logic, pipeline, pattern recognition, ....- lots of local 'region-of-interest' analysis. Speeds real-time imaging. 48 channels/chip

# Status of First (VCO) Chip Submission

- Were on path for Feb 26 MOSIS submission of VCO with 8HP...
- Tapeout/Details available at <http://edg.uchicago.edu/psec/>
- Starting on Phase-Detector; then Charge-Pump; then Const. Fraction Discriminator- long ways to go! (we are beginners...)

# Questions (we are just starting)

1. What determines the ultimate limits?
2. Are there other techniques? (e.g. SiPM's, ...)?
3. Could one integrate the electronics into the MCP structure- 3D silicon (Paul Horn, Pierre Jarron)?
4. Will the capacitive return work?
5. How to calibrate the darn thing (a big system)?!
6. How to distribute the clock
7. What is the time structure of signals from crystals in PET? (photon arrival at psec level)
8. Can we join forces with others and go faster?

# The End-

# Backup Slides

# Beam test result

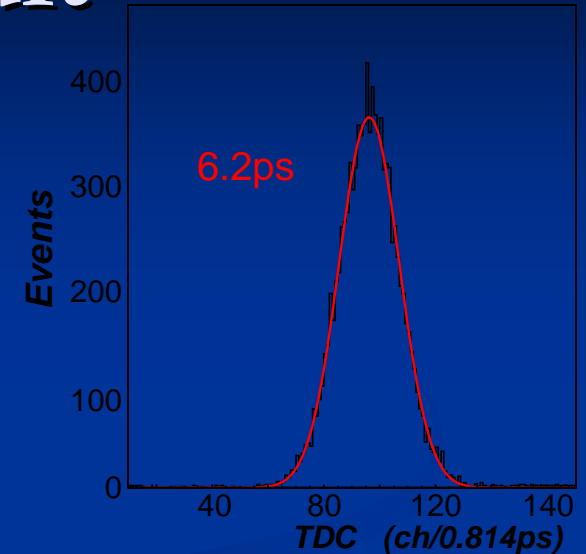

Jerry Va'vra has  
new similar results  
(see ref's)

## ■ With 10mm quartz radiator

- +3mm quartz window
- Number of photons  $\sim 180$
- Time resolution = 6.2ps
- Intrinsic resolution  $\sim 4.7ps$

## ■ Without quartz radiator

- 3mm quartz window
- Number of photons  $\sim 80$ 
  - Expectation  $\sim 20$  photo-electrons
- Time resolution = 7.7ps

# PET, TOFPET & SPECT

Saclay, France March 8-9 2007

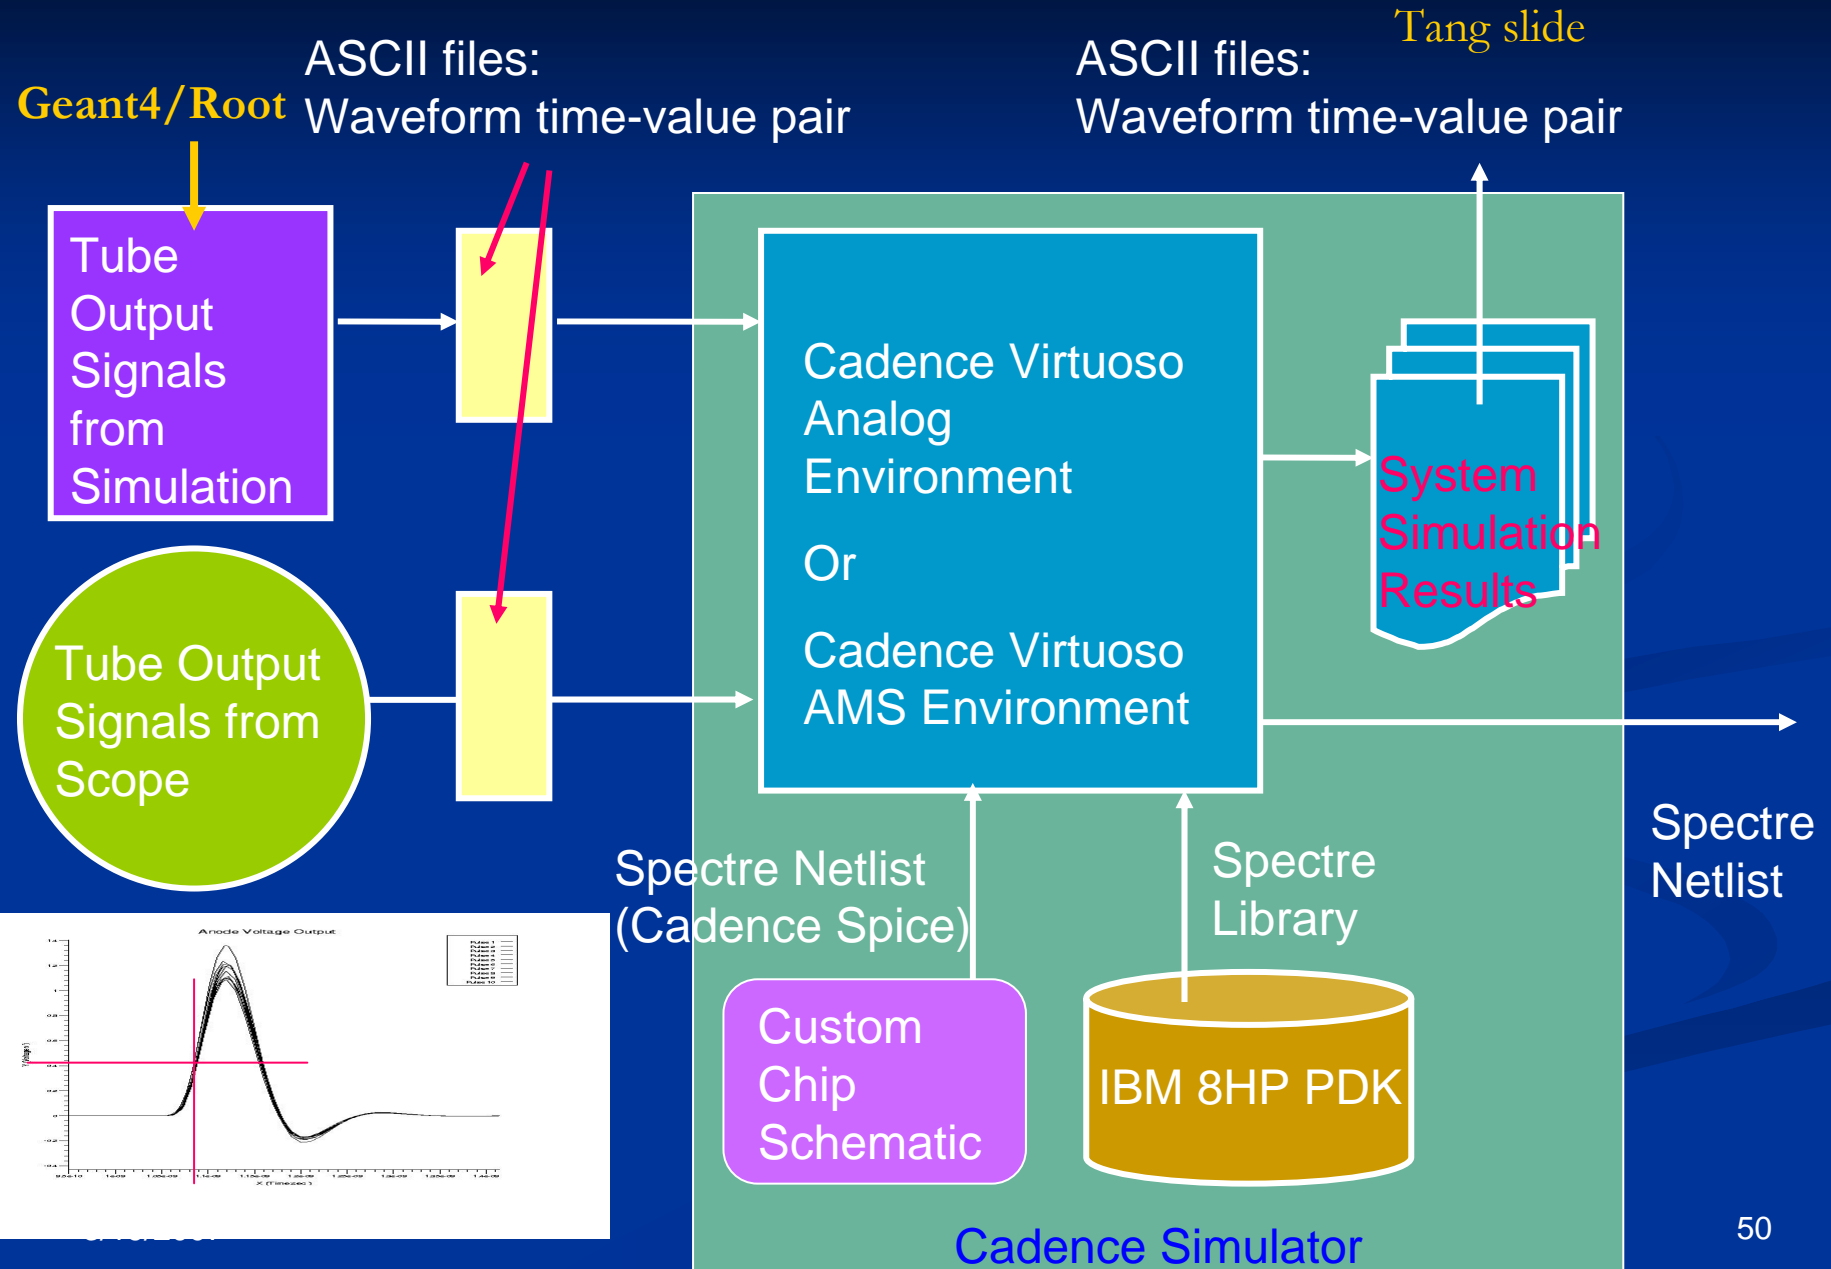

# The Future- Triggering?

$T\text{-}\bar{T} \rightarrow W^+bW^-b\bar{b}$

Can we follow the color flow of the partons themselves?

# Interface to Other Simulation Tools

# Questions on Simulation-Tasks (for discussion at Saclay)

1. Framework- what is the modern CS approach?
2. Listing the modules- is there an archetype set of modules?
3. Do we have any of these modules at present?
4. Can we specify the interfaces between modules- info and formats?
5. Do we have any of these interfaces at present?
6. Does it make sense to do Medical Imaging and HEP in one framework?
7. Are there existing simulations for MCP's?

# What sets the 1 psec goal for HEP?

## Separation with a 1.5-m Radius Solenoid (CDF)

Figure 4: Contours of 1-sigma separation for pions, kaons, and protons versus the time resolution of the particle flight time over a 1.5-meter path for a detector with 1psec resolution.

## Getting the Start Time: $t_0$ .

Collisions at the Tevatron (e.g.) have a distribution in times with a sigma of  $\approx 1.4$  nsec (1.4 thousand psec's). Rather than measure the start time,  $t_0$ , at the origin, we fit the tracks from a single vertex for the  $t_0$ .

At present we do this with the tracking chamber (COT), with a resolution on the order of a nsec.

At CDF:  $t_0$  is correlated with  $z_{vertex}$ ! (From the new TAMU EM timing system in CDF (Goncharov, Krutelyov, Toback)).

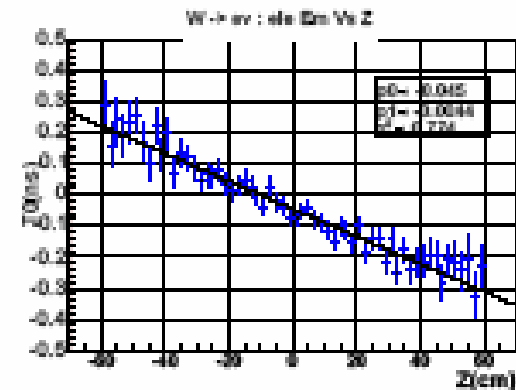

Figure 5:

Point is that each vertex has a time— fitting the tracks can tie charged particles to vertices. Fitting photons likewise is also possible if we know L, as we know beta.

# Simulation for Coil Showering and various PMTs

- Right now, we have a simulation using GEANT4, ROOT, connected by a python script
- GEANT4:  $\pi^+$  enters solenoid, e- showers
- ROOT: MCP simulation - get position, time of arrival of charge at anode pads
- Both parts are approximations
- Could we make this more modular?
- Could we use GATE (Geant4 Application for Tomographic Emission) to simplify present and future modifications?
- Working with Chin-tu Chen, Chien-Minh Kao and group, - they know GATE well. And, new, at Saclay Irene Buvat attended and expressed good intentions in getting the OpenGATE Collaboration involved.

# Present Status of ANL/UC

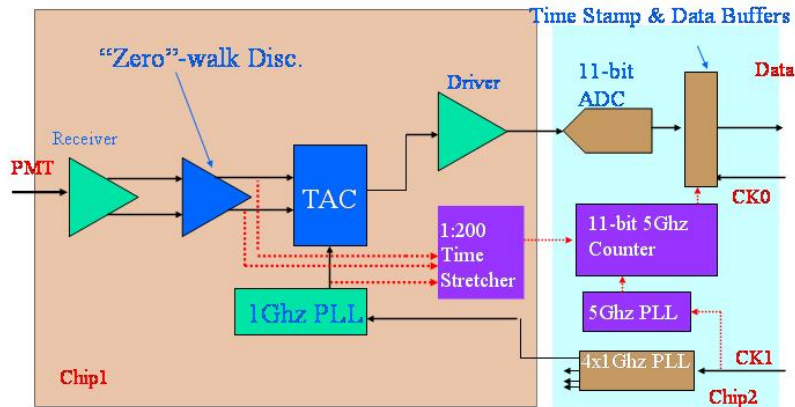

1. Have a simulation of Cherenkov radiation in MCP into electronics
2. Have placed an order with Burle/Photonis- have the 1<sup>st</sup> of 4 tubes and have a good working relationship (their good will and expertise is a major part of the effort): 10 micron tube in the works; optimized versions discussed;
3. Harold and Tang have a good grasp of the overall system problems and scope, and have a top-level design plus details
4. Have licences and tools from IHP and IBM working on our work stations. Made VCO in IHP; have design in IBM 8HP process.
5. Have modeled DAQ/System chip in Altera (Jakob Van Santen); ANL will continue in faster format.
6. ANL has built a test stand with working DAQ, very-fast laser, and has made contact with advanced accel folks:(+students)
7. Have established strong working relationship with Chin-Tu Chen's PET group at UC; Have proposed a program in the application of HEP to med imaging.
8. Have found Greg Sellberg and Hogan at Fermilab to offer expert precision assembly advice and help (wonderful tools and talent!).
9. Are working with Jerry V'avra (SLAC); draft MOU with Saclay

# Simulation of Circuits (Tang)

## Approaches & Possibilities

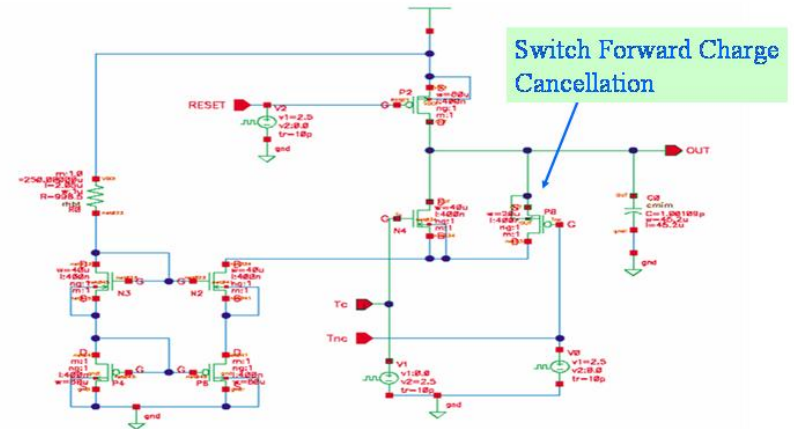

From Harold's talk, we will build two Chips for Tube Readout

(1) psFront-end (2) psTransport

## SIM-IV: Time-to-Amplitude (TAC) Schematics

Based on IHP 0.25 $\mu$ m BiCMOS Process

## SIM-II: Zero-Crossing Voltage Comparator Schematics

Based on IHP 0.25 $\mu$ m BiCMOS Process

## SIM-IV: TAC Outputs vs. Tw Inputs

Sweep Tw from 1ns to 1.01ns with 1ps

Increment

Psec T

## $\pi^+$ Generation, Coil Showering GEANT4

Input Source code, Macros Files

- Geometry
- Materials
- Particle:
  - Type
  - Energy
  - Initial Positions, Momentum
- Physics processes
- Verbose level

Have position,  
time, momentum,  
kinetic energy of  
each particle for each step  
(including upon entrance to PMT)

## PMT/MCP GEANT4 - swappable

- Need to redo geometry  
(local approx.. cylinder)
- Need to redo field
- Need to connect two  
modules (python script in place  
for older simulation)

**Pure GEANT4**

3/19/2007

Get position, time  
IBM Psec Timing

- Input Macros Files - precompiled source

$\pi^+$  Generation  
GATE

Physics processes  
macros file

Solenoid Showering  
GATE

But, we need to write  
Source code for  
Magnetic Field, recompile

PMT/MCP  
GATE - swap with  
default "digitization"  
module

# A real CDF event- r-phi view

Key idea- fit  $t_0$  (start) from all tracks

# The Future of Psec Timing-

From the work of the Nagoya Group, Jerry Va'vra, and ourselves it looks that the psec goal is not impossible. It's a new field, and we have made first forays, and understand some fundamentals (e.g. need no bounces and short distances), but it's entirely possible, even likely, that there are still much better ideas out there.

## Big Questions:

- What determines the ultimate limits?
- Are there other techniques? (e.g. all Silicon)?
